

Rotational Kinetic Energy

There are two types of speeds: linear and angular. On the left we show a mass with a linear speed v . Its linear kinetic energy is $\frac{1}{2}mv^2$. In the center we show a homogeneous disk revolving about its own center. Its rotation kinetic energy is $\frac{1}{2}I\omega^2$.

On the right we show a homogenous disk that is rolling from left to right. The disk has kinetic energy because of its linear speed v and also has kinetic energy because of its angular speed ω .

To develop the expression for rotational kinetic energy, we consider a small bit of mass of a homogeneous cylinder that is located at a distance r from the center. The cylinder is rotating about its own center, which is not moving. The angular speed is ω . This bit of mass has linear kinetic energy because of its instantaneous linear speed.

10-8 Rotational Kinetic Energy

Torque Torque Torque Torque Torque Torque Torque Torque Torque

- Translational Kinetic Energy

$$K = \frac{1}{2}mv^2$$

Recall $v=r\omega$

$$K = \frac{1}{2}m(r\omega)^2 = \frac{1}{2}mr^2\omega^2$$

$$K_{rotational} = \frac{1}{2}I\omega^2, \text{ where } I=mr^2$$

Additionally;

$$KE_{\text{total}} = \frac{1}{2} I_{\text{CM}} \omega^2 + \frac{1}{2} M v_{\text{CM}}^2$$

rotational KE
translational KE

The total kinetic energy of a rolling object is the sum of the *rotational* kinetic energy about the center of mass and the *translational* kinetic energy of the center of mass.

Therefore;

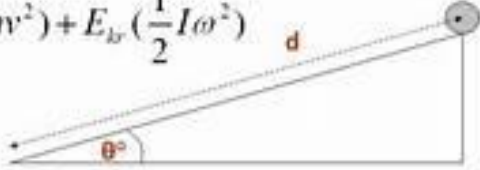

Rotational Kinetic Energy E_{kr} (J)

When an object rotates it has E_{kr} . Objects can have both linear & rotational kinetic energy

$$E_k = \frac{1}{2} m v^2 + \frac{1}{2} I \omega^2$$

E_k of linear motion (center-of-mass)
 E_{kr} due to rotation

Assuming conservation of Mechanical energy holds then:

$$E_p (mgh) = E_k \left(\frac{1}{2} m v^2 \right) + E_{kr} \left(\frac{1}{2} I \omega^2 \right)$$

27. A homogeneous cylinder whose mass is 6 kg has a radius of 10 cm. It is revolving at 10 radians per second. What is the rotational kinetic energy of the cylinder?

(Note: $I = \frac{1}{2} m r^2$; for a cylinder.)

28. Find the total kinetic energy of a 2.0 m diameter hoop rolling, without slipping, with a speed of 4.0 m/s. The homogeneous mass of the hoop is 1.2 kg and the moment of inertia for a hoop is $I = mr^2$. (Remember $v = \omega r$).

29. Find the total kinetic energy of a 1.0 m diameter ball rolling, without slipping, with a speed of 10.0 m/s. The homogeneous mass of the ball is 20.0 kg and the moment of inertia for a ball is $I = \frac{2}{5}mr^2$. (Remember $v = \omega r$).

30. A homogeneous 6.25 kg cylinder, whose radius is 10.8 cm, rolls without slipping, down an inclined plane a vertical distance of 1.57 meters. What is its speed at the bottom if it starts from rest? Note: $I = \frac{1}{2}mr^2$ for a cylinder and $v = \omega r$.

31. A homogeneous 5.3 kg ball rolls, without slipping, down an inclined plane, a vertical distance of 4.7 meters. What is its speed at the bottom if it starts from rest? Note: $I = \frac{2}{5}mr^2$ for a ball and $v = \omega r$.

32. Find the angular momentum of a hollow, thin sphere with a radius of 0.051 m, a mass of 0.16 kg, and an angular speed of rotation about its center of 4.2 rad/s.

(Note: angular momentum = $L = I\omega$. and $I = \frac{2}{3} m r^2$ for a hollow sphere)

33. A point mass of 0.50 kg is mounted on the end of a very light rod 2.0 meters long. It's angular speed is 5 radians per second. What torque should be applied for 10 seconds to increase the angular speed to 20 radians per second?

Note: (Angular impulse-momentum equation: $\tau \Delta t = \Delta(I\omega)$ and $I = mr^2$)

34. A yo-yo experiences a torque of 3.9×10^{-2} N m as it falls for 1.3 seconds.

(a) Find the angular momentum of the yo-yo if it starts from rest.

Note: (Angular impulse-momentum equation: $\tau \Delta t = \Delta(I\omega)$ and $I = mr^2$)

(b) If the yo-yo has a homogeneous mass of 0.20 kg, a radius of 0.030 m, and a moment of inertia of $\frac{1}{2}mr^2$, find its angular speed.
